Couchbase Server [32|64bit]

Couchbase Server is a simple, fast, elastic, open-source NoSQL database. Automatically distributes data across commodity servers or virtual machines. Built-in managed object caching enables apps to read and write data with sub-millisecond latency. With no schema to manage, Couchbase effortlessly accommodates changing data management requirements. It is easy to deploy and manage in production with its advanced monitoring and admin GUI. Your browser does not support the video tag. Couchbase Server Requirements: Couchbase Server may be installed on the same machine on which it runs, or it may be installed in a separate machine. Couchbase Server is compatible with Windows, Linux, and Mac operating systems. It is free to download and use, and is distributed under the Apache 2.0 license. In order to obtain commercial support for Couchbase Server, you must become a Couchbase Partner. If you'd like to learn more about what it is Couchbase can do for your app, click the 'Demo' link below to watch a video about how Couchbase works. In addition to Couchbase Server, you can also access Couchbase's features through the Couchbase Mobile SDK. We have tested Couchbase Server 1.8.0 and it is failing to login and we think it might be a ssl key issue. We use a wildcard cert in the ssl configuration, but still getting the error: { "error" : "java.io.IOException: Unauthorized" } We can access (using curl/wget) using the browser, so we think it might be a ssl cert issue. Is there a way we can generate our own ssl cert for Couchbase to use? A: So, the best answer we got is to disable client authentication, even though we use a wildcard cert (so it should just be using the server cert). Also disable client certs, and use the cert files provided with Couchbase Server. So, if you're using the dev

--- This simulation is used to study the effects of trade policy uncertainty on the real estate market. The market is presented as a simple single buyer and seller model. Details: ------------------------------------- The simulation lasts 5 years, starting in year 0. During the years 0-3, the government implemented a 'bear market' intervention that capped the real estate price at RRP +15%. From years 3-5 the government implemented a 'bull market' intervention that increased the price by 5%. In year 3, one of the two initial investors changed their mind and decided not to participate in the real estate market. The market conditions were simulated in parallel, as usual, with one half of the simulation consisting of only the buyer and seller, and the other half consisting of the buyer and seller with an additional investor. The market conditions of year 0 were implemented for the whole run. Note: --- The simulation cannot work without data on the real estate market. It will therefore fail with no data. User interaction: --- The simulation runs until year 3. You can change the data used as input by clicking 'Change Data' on the menu bar, where you can also run a simulation on a subset of the data by selecting years 0-3 or year 0. Code and data dependencies: ------------------------------------- The input data is used from the file real_estate.csv. Outputs: ------------------------------------- The simulation results are presented in the file simulation_results.csv. The generated data can be accessed using a browser. Bugs: ------------------------------------- There is no known bug in the simulation itself. Dependencies: -------------------------- * No dependencies. Uncertainty in the Demand for Real Estate --- Introduction The classical rational decision-making model of the real estate market assumes that the buyers and sellers have the same information as the market. However, from the theoretical point of view, it is possible that the true value of the house depends on the buyer's and seller's opinions of the future demand for real estate. The real estate markets are also affected by market and political shocks. These market and political shocks are not easy to model and cannot be predicted, and there is evidence that they have already started to affect the real estate market. Therefore, it is natural to model the decision to buy a house as a real option. In this simulation, we assume that the demand for real estate is influenced by fluctuations in three main factors: - Inflation in the future - Government policies (such as taxes, and minimum wage) - Regulatory policies (such as easements and zoning) In our model, we assume that the perceived demand for real estate is equal to the true demand for real estate. One initial investor One initial investor has decided to invest in a house in the year 0
